## Preface

# 1. Document Conventions

This manual uses several conventions to highlight certain words and phrases and draw attention to specific pieces of information.

In PDF and paper editions, this manual uses typefaces drawn from the [Liberation Fonts](https://fedorahosted.org/liberation-fonts/) [https://fedorahosted.org/liberation-fonts/] set. The Liberation Fonts set is also used in HTML editions if the set is installed on your system. If not, alternative but equivalent typefaces are displayed. Note: Red Hat Enterprise Linux 5 and later includes the Liberation Fonts set by default.

## 1.1. Typographic Conventions

Four typographic conventions are used to call attention to specific words and phrases. These conventions, and the circumstances they apply to, are as follows.

**Mono-spaced Bold**

Used to highlight system input, including shell commands, file names and paths. Also used to highlight key caps and key-combinations. For example:

To see the contents of the file `my_next_bestselling_novel` in your current working directory, enter the `cat my_next_bestselling_novel` command at the shell prompt and press **Enter** to execute the command.

The above includes a file name, a shell command and a key cap, all presented in Mono-spaced Bold and all distinguishable thanks to context.

Key-combinations can be distinguished from key caps by the hyphen connecting each part of a key-combination. For example:

Press **Enter** to execute the command.

Press **Ctrl+Alt+F1** to switch to the first virtual terminal. Press **Ctrl+Alt+F7** to return to your X-Windows session.

The first sentence highlights the particular key cap to press. The second highlights two sets of three key caps, each set pressed simultaneously.

If source code is discussed, class names, methods, functions, variable names and returned values mentioned within a paragraph will be presented as above, in **Mono-spaced Bold**. For example:

File-related classes include `filesystem` for file systems, `file` for files, and `dir` for directories. Each class has its own associated set of permissions.

### Proportional Bold

This denotes words or phrases encountered on a system, including application names; dialogue box text; labelled buttons; check-box and radio button labels; menu titles and sub-menu titles. For example:

Choose **System > Preferences > Mouse** from the main menu bar to launch **Mouse Preferences**. In the **Buttons** tab, click the **Left-handed mouse** check box and click **Close** to switch the primary mouse button from the left to the right (making the mouse suitable for use in the left hand).

To insert a special character into a **gedit** file, choose **Applications > Accessories > Character Map** from the main menu bar. Next, choose **Search > Find** from the **Character Map** menu bar, type the name of the character in the **Search** field and click **Next**. The character you sought will be highlighted in the **Character Table**. Double-click this highlighted character to place it in the **Text to copy** field and then click the **Copy** button. Now switch back to your document and choose **Edit > Paste** from the **gedit** menu bar.

The above text includes application names; system-wide menu names and items; application-specific menu names; and buttons and text found within a GUI interface, all presented in Proportional Bold and all distinguishable by context.

Note the **>** shorthand used to indicate traversal through a menu and its sub-menus. This is to avoid the difficult-to-follow 'Select **Mouse** from the **Preferences** sub-menu in the **System** menu of the main menu bar' approach.

*Mono-spaced Bold Italic Of Proportional Bold Italic*

Whether Mono-spaced Bold or Proportional Bold, the addition of Italics indicates replaceable or variable text. Italics denotes text you do not input literally or displayed text that changes depending on circumstance. For example:

To connect to a remote machine using ssh, type `ssh username@domain.name` at a shell prompt. If the remote machine is `example.com` and your username on that machine is john, type `ssh john@example.com`.

The `mount -o remount file-system` command remounts the named file system. For example, to remount the `/home` file system, the command is `mount -o remount /home`.

To see the version of a currently installed package, use the `rpm -q package` command. It will return a result as follows: `package-version-release`.

Note the words in bold italics above `username`, `domain.name`, `file-system`, `package`, `version` and `release`. Each word is a placeholder, either for text you enter when issuing a command or for text displayed by the system.

Aside from standard usage for presenting the title of a work, italics denotes the first use of a new and important term. For example:

When the Apache HTTP Server accepts requests, it dispatches child processes or threads to handle them. This group of child processes or threads is known as

a *server-pool*. Under Apache HTTP Server 2.0, the responsibility for creating and maintaining these server-pools has been abstracted to a group of modules called *Multi-Processing Modules (MPMs)*. Unlike other modules, only one module from the MPM group can be loaded by the Apache HTTP Server.

## 1.2. Pull-quote Conventions

Two, commonly multi-line, data types are set off visually from the surrounding text.

Output sent to a terminal is set in `Mono-spaced Roman` and presented thus:

```
books      Desktop  documentation  drafts  mss    photos  stuff  svn
books_tests Desktop1  downloads      images  notes  scripts svgs
```

Source-code listings are also set in `Mono-spaced Roman` but are presented and highlighted as follows:

```
package org.jboss.book.jca.ex1;

import javax.naming.InitialContext;

public class ExClient
{
    public static void main(String args[])
        throws Exception
    {
        InitialContext iniCtx = new InitialContext();
        Object      ref  = iniCtx.lookup("EchoBean");
        EchoHome    home = (EchoHome) ref;
        Echo        echo = home.create();

        System.out.println("Created Echo");

        System.out.println("Echo.echo('Hello') = " + echo.echo("Hello"));
    }
}
```

## 1.3. Notes and Warnings

Finally, we use three visual styles to draw attention to information that might otherwise be overlooked.

### Note

A note is a tip or shortcut or alternative approach to the task at hand. Ignoring a note should have no negative consequences, but you might miss out on a trick that makes your life easier.

### Important

Important boxes detail things that are easily missed: configuration changes that only apply to the current session, or services that need restarting before an update will apply. Ignoring Important boxes won't cause data loss but may cause irritation and frustration.

### Warning

A Warning should not be ignored. Ignoring warnings will most likely cause data loss.

## 2. Provide feedback to the authors!

If you find a typographical error in this manual, or if you have thought of a way to make this manual better, we would love to hear from you! Please submit a report in the the [Issue Tracker](http://code.google.com/p/mobicents/issues/list) [http://code.google.com/p/mobicents/issues/list], against the product **Mobicents JAIN SLEE XDM Client Enabler**, or contact the authors.

When submitting a bug report, be sure to mention the manual's identifier: JAIN\_SLEE\_ENABLER\_XDMClient\_User\_Guide

If you have a suggestion for improving the documentation, try to be as specific as possible when describing it. If you have found an error, please include the section number and some of the surrounding text so we can find it easily.

# Introduction to Mobicents JAIN SLEE XDM Client Enabler

The JAIN SLEE XDM Client Enabler allows JAIN SLEE Applications to interact with XDM Servers, hiding the network protocol complexity. The Enabler consists in an SBB which can be used in child relations, with a simple asynchronous interface.

The XDM Server is a functional element used in OMA and 3GPP SIP Presence networks, to manage public user documents, in the XML format. An example of such documents is the user's buddy list. Essentially the XDM Server is an XCAP Server with additional interfaces, such as SIP Event Package XCAP Diff, which allows SIP subscriptions on changes done to documents through XCAP.

# Setup

## 2.1. Pre-Install Requirements and Prerequisites

Ensure that the following requirements have been met before continuing with the install.

### 2.1.1. Hardware Requirements

The Enabler doesn't change the Mobicents JAIN SLEE Hardware Requirements, refer to Mobicents JAIN SLEE documentation for more information.

### 2.1.2. Software Prerequisites

The Enabler requires Mobicents JAIN SLEE properly set, with the XCAP Client Resource Adaptor deployed.

## 2.2. Mobicents JAIN SLEE XDM Client Enabler Source Code

This section provides instructions on how to obtain and build the XDM Client Enabler from source code.

### 2.2.1. Release Source Code Building

#### 1. Downloading the source code

#### Important

Subversion is used to manage its source code. Instructions for using Subversion, including install, can be found at <http://svnbook.red-bean.com>

Use SVN to checkout a specific release source, the base URL is <http://mobicents.googlecode.com/svn/tags/servers/jain-slee/2.x.y/enablers/xdm-client/>, then add the specific release version, lets consider 1.0.0.CR3.

```
[usr]$ svn co http://mobicents.googlecode.com/svn/tags/servers/jain-slee/2.x.y/enablers/xdm-client/1.0.0.CR3 slee-enabler-xdm-client-1.0.0.CR3
```

### 2. Building the source code

#### Important

Maven 2.0.9 (or higher) is used to build the release. Instructions for using Maven2, including install, can be found at <http://maven.apache.org>

Use Maven to build the deployable unit binary.

```
[usr]$ cd slee-enabler-xdm-client-1.0.0.CR3  
[usr]$ mvn install
```

Once the process finishes you should have the `deployable-unit` jar file in the `target` directory, if Mobicents JAIN SLEE is installed and environment variable `JBOSS_HOME` is pointing to its underlying JBoss Application Server directory, then the deployable unit jar will also be deployed in the container.

#### Important

This procedure does not install the Enabler's dependencies

### 2.2.2. Development Trunk Source Building

Similar process as for [Section 2.2.1, "Release Source Code Building"](#), the only change is the SVN source code URL, which is <http://mobicents.googlecode.com/svn/trunk/servers/jain-slee/enablers/xdm-client>.

## 2.3. Installing Mobicents JAIN SLEE XDM Client Enabler

To install the Enabler simply execute provided ant script `build.xml` default target:

```
[usr]$ ant
```

The script will copy the Enabler's deployable unit jar to the `default` Mobicents JAIN SLEE server profile deploy directory, to deploy to another server profile use the argument `-Dnode=`.

### Important

This procedure also installs the Enabler's dependencies.

## 2.4. Uninstalling Mobicents JAIN SLEE XDM Client Enabler

To uninstall the Enabler simply execute provided ant script `build.xml` `undeploy` target:

```
[usr]$ ant undeploy-all
```

The script will delete the Enabler's deployable unit jar from the `default` Mobicents JAIN SLEE server profile deploy directory, to undeploy from another server profile use the argument `-Dnode=`.

### Important

This procedure also uninstalls the Enabler's dependencies.

---

# Integrating the Mobicents JAIN SLEE XDM Client Enabler

This chapter explains how to setup a JAIN SLEE Service Sbb to use the Enabler.

In short terms, a Service's Sbb will define the Enabler's Sbb as a child, and to achieve that it will need to setup the XML Descriptor, Abstract Class and SbbLocalObject interface.

## Important

The Service's Sbb will be referred as the Parent Sbb in the following sections.

## Important

Mobicents JAIN SLEE XDM Client depends on Mobicents JAIN SLEE SIP Subscription Enabler to provide `XCAP Diff` functionality.

## 3.1. The Parent's SbbLocalObject Interface

The Mobicents JAIN SLEE XDM Client Enabler Sbb provides asynchronous callbacks to the Parent's Sbb, and that can only be achieved if the Parent's SbbLocalObject extends a specific Java interface, deployed also by the Enabler. The Enabler uses the Parent's SbbLocalObject when a callback to the Parent's Sbb is needed.

The SbbLocalObject which must be used or extended by the Parent's Sbb is named `org.mobicents.slee.enabler.xdmc.XDMClientParentSbbLocalObject`, which extends the `org.mobicents.slee.SbbLocalObjectExt` and `org.mobicents.slee.enabler.xdmc.XDMClientParent` interfaces, the latter declares the callbacks which must be implemented in the Parent's Sbb Abstract Class:

```
package org.mobicents.slee.enabler.xdmc;

public interface XDMClientParent {

    public void getResponse(URI uri, int responseCode, String mimetype,
        String content, String eTag);

    public void putResponse(URI uri, int responseCode, String responseContent,
        String eTag);
```

```
public void deleteResponse(Uri uri, int responseCode,
    String responseContent, String eTag);

public void subscribeFailed(int responseCode,
    XDMClientChildSbbLocalObject sbbLocalObject, String notifier);

public void resubscribeFailed(int responseCode,
    XDMClientChildSbbLocalObject sbbLocalObject, String notifier);

public void unsubscribeFailed(int responseCode,
    XDMClientChildSbbLocalObject sbbLocalObject, String notifier);

public void subscriptionTerminated(XDMClientChildSbbLocalObject sbbLocalObject,
    String notifier, TerminationReason reason);

public void subscriptionNotification(XcapDiff xcapDiff, SubscriptionStatus status);

}
```

The `getResponse(Uri, int, String, String, String)` method:

Callback from the Enabler providing the response for an XML resource GET request.

The `putResponse(Uri, int, String, String)` method:

Callback from the Enabler providing the response for an XML resource PUT request.

The `deleteResponse(Uri, int, String, String)` method:

Callback from the Enabler providing the response for an XML resource DELETE request.

The `public void subscribeFailed(int responseCode, XDMClientChildSbbLocalObject sbbLocalObject, String notifier)` method:

Callback from the Enabler indicating failed attempt to subscribe to XCAP Diff event package.

The `public void resubscribeFailed(int responseCode, XDMClientChildSbbLocalObject sbbLocalObject, String notifier)` method:

Callback from the Enabler indicating failed resubscribe attempt.

The `public void unsubscribeFailed(int responseCode, XDMClientChildSbbLocalObject sbbLocalObject, String notifier)` method:

Callback from the Enabler indicating failure to unsubscribe to XCAP Diff event package.

The `public void subscriptionTerminated(XDMClientChildSbbLocalObject sbbLocalObject, URI notifier, TerminationReason reason)` method:

Callback from the Enabler informing user that subscription has been terminated. This callback can be triggered by various reasons, however in always indicates that server expunged subscription state.

The `public void subscriptionNotification(XcapDiff xcapDiff, SubscriptionStatus status)` method:

Callback from the Enabler indicating change in resource to which enabler subscribed. Initial subscription success will trigger this callback with current state of resources.

## 3.2. The Parent's Sbb Abstract Class

The Parent Sbb Abstract Class must implement the callbacks on it's SbbLocalObject, that is, must implement the `org.mobicens.slee.enabler.xdmc.XDMClientParent` interface discussed in last section.

The Enabler's Sbb is a Child Sbb, and JAIN SLEE 1.1 Child Relations requires an abstract method in the Sbb Abstract Class, to retrieve the `org.mobicens.slee.ChildRelationExt` object, which is used to create or access specific Child Sbbs. This method should be:

```
public abstract ChildRelationExt getXDMClientChildRelation();
```

## 3.3. The Parent's Sbb XML Descriptor

The Parent's Sbb must define a reference to the Enabler's Child Sbb, declare which is the method name to get the related ChildRelation object, and also ensure the SbbLocalObject interface is defined correctly.

A reference to the Enabler's Child Sbb is defined right after the Parent's Sbb Vendor ID element, using the following XML element:

```
<sbb-ref>
  <sbb-name>XDMClientChildSbb</sbb-name>
  <sbb-vendor>org.mobicens</sbb-vendor>
  <sbb-version>1.0</sbb-version>
  <sbb-alias>xdmClientChildSbb</sbb-alias>
</sbb-ref>
```

The method name to get the Enabler's ChildRelation object must be defined after the CMP Fields (if any), this XML element links the sbb-alias previously defined with the abstract method declared in the Parent's Sbb Abstract Class:

```
<get-child-relation-method>
  <sbb-alias-ref>xdmClientChildSbb</sbb-alias-ref>
  <get-child-relation-method-name>getXDMClientChildRelation</get-child-relation-method-
name>
  <default-priority>0</default-priority>
</get-child-relation-method>
```

Finally, after the `sbb-abstract-class` element the Parent's SbbLocalObject interface name is defined:

```
<sbb-local-interface>
  <sbb-local-interface-name>...</sbb-local-interface-name>
</sbb-local-interface>
```

# Using the Mobicents JAIN SLEE

## XDM Client Enabler

In the last chapter we integrated the Enabler in the JAIN SLEE Service's Sbb, the Parent Sbb, in this chapter it is explained how to use the Enabler's Sbb, the Child Sbb.

### 4.1. The Child's SbbLocalObject Interface

The Mobicents JAIN SLEE XDM Client Enabler Sbb, the Child Sbb, implements the `org.mobicents.slee.enabler.xdmc.XDMClientChildSbbLocalObject`, which extends the `org.mobicents.slee.SbbLocalObjectExt` and `org.mobicents.slee.enabler.xdmc.XDMClientChild` interfaces, the latter declares the methods which can be used to interact with the XDM Server:

```
package org.mobicents.slee.enabler.xdmc;

import java.io.IOException;
import java.net.URI;

import org.mobicents.xcap.client.auth.Credentials;
import org.mobicents.xcap.client.auth.CredentialsFactory;

public interface XDMClientChild {

    public CredentialsFactory getCredentialsFactory();

    public void get(URI uri, Credentials credentials) throws IOException;

    public void get(URI uri, String assertedUserId) throws IOException;

    public void put(URI uri, String mimetype, byte[] content,
        Credentials credentials) throws IOException;

    public void put(URI uri, String mimetype, byte[] content,
        String assertedUserId) throws IOException;

    public void putIfMatch(URI uri, String eTag, String mimetype,
        byte[] content, Credentials credentials) throws IOException;

    public void putIfMatch(URI uri, String eTag, String mimetype,
        byte[] content, String assertedUserId) throws IOException;
```

```
public void putIfNoneMatch(Uri uri, String eTag, String mimeType,
    byte[] content, Credentials credentials) throws IOException;

public void putIfNoneMatch(Uri uri, String eTag, String mimeType,
    byte[] content, String assertedUserId) throws IOException;

public void delete(Uri uri, Credentials credentials) throws IOException;

public void delete(Uri uri, String assertedUserId) throws IOException;

public void deleteIfMatch(Uri uri, String eTag, Credentials credentials)
    throws IOException;

public void deleteIfMatch(Uri uri, String eTag, String assertedUserId)
    throws IOException;

public void deleteIfNoneMatch(Uri uri, String eTag, Credentials credentials)
    throws IOException;

public void deleteIfNoneMatch(Uri uri, String eTag, String assertedUserId)
    throws IOException;

public void subscribe(String subscriber, String notifier, int expires, String[]
    resourceURIs) throws SubscriptionException;

public void unsubscribe(String subscriber, String notifier);
}
```

The `getCredentialsFactory()` method:

Retrieves the factory to create HTTP Digest authentication credentials, to be used in requests sent to the XDM Server.

The `get(Uri, Credentials)` method:

Retrieves the XML resource from the XDM Server, for the specified URI, using the specified HTTP Digest Credentials. Response is provided through parent's callback `getResponse(...)`.

The `get(Uri, String)` method:

Retrieves the XML resource from the XDM server, for the specified URI, asserting the user id. Response is provided through parent's callback `getResponse(...)`.

The `put(Uri, String, byte[], Credentials)` method:

Puts the specified content in the XDM Server, using the specified HTTP Digest Credentials. Response is provided through parent's callback `putResponse(...)`.

The `put(Uri, String, byte[], String)` method:

Puts the specified content in the XDM Server, asserting the user id. Response is provided through parent's callback `putResponse(...)`.

The `putIfMatch(Uri, String, String, byte[], Credentials)` method:

Puts the specified content in the XDM Server, using the specified HTTP Digest Credentials, if the ETag matches the document in the server. Response is provided through parent's callback `putResponse(...)`.

The `putIfMatch(Uri, String, String, byte[], String)` method:

Puts the specified content in the XDM Server, asserting the user id, if the ETag matches the document in the server. Response is provided through parent's callback `putResponse(...)`.

The `putIfNoneMatch(Uri, String, String, byte[], Credentials)` method:

Puts the specified content in the XDM Server, using the specified HTTP Digest Credentials, if the ETag does not matches the document in the server. Response is provided through parent's callback `putResponse(...)`.

The `putIfNoneMatch(Uri, String, String, byte[], String)` method:

Puts the specified content in the XDM Server, asserting the user id, if the ETag does not matches the document in the server. Response is provided through parent's callback `putResponse(...)`.

The `delete(Uri, Credentials)` method:

Deletes the document in the XDM Server, using the specified HTTP Digest Credentials. Response is provided through parent's callback `deleteResponse(...)`.

The `delete(Uri, String)` method:

Deletes the document in the XDM Server, asserting the user id. Response is provided through parent's callback `deleteResponse(...)`.

The `deleteIfMatch(Uri, String, Credentials)` method:

Deletes the document in the XDM Server, using the specified HTTP Digest Credentials, if the ETag matches the document in the server. Response is provided through parent's callback `deleteResponse(...)`.

The `deleteIfMatch(Uri, String, String)` method:

Deletes the document in the XDM Server, asserting the user id, if the ETag matches the document in the server. Response is provided through parent's callback `deleteResponse(...)`.

The `deleteIfNoneMatch(Uri, String, Credentials)` method:

Deletes the document in the XDM Server, using the specified HTTP Digest Credentials, if the ETag does not matches the document in the server. Response is provided through parent's callback `deleteResponse(...)`.

The `deleteIfNoneMatch(Uri, String, String)` method:

Deletes the document in the XDM Server, asserting the user id, if the ETag does not matches the document in the server. Response is provided through parent's callback `deleteResponse(...)`.

The `public void subscribe(String subscriber, String notifier, int expires, String[] resourceURIs)` throws `SubscriptionException` method:

Requests Enabler to subscribe XCAP Diff events. Enabler subscribes to resources from passed list.

The `public void unsubscribe(String subscriber, String notifier)` method:

Reqeusts enabler to unsubscribe from resources.

## 4.2. Creating And Retrieving The Child Sbb

The Child Relation in the Parent Sbb Abstract Class is used to create and retrieve the Child Sbb:

```
XDMClientChildSbbLocalObject sbb = null;
// creation
try {
    sbb = (XDMClientChildSbbLocalObject) getXDMClientChildRelation().create(childName);
}
catch (Exception e) {
    tracer.severe("Failed to create child sbb", e);
}
// retrieval
try {
    sbb = (XDMClientChildSbbLocalObject) getXDMClientChildRelation().get(childName);
}
catch (Exception e) {
    tracer.severe("Failed to retrieve child sbb", e);
}
```

## 4.3. Creating URIs for XDM Server Resources

XCAP URIs are complex, but these can be easily created with the XCAP Client API, included with Mobicents JAIN SLEE XCAP Client Resource Adaptor. Please refer to it's documentation on how to use such API.

# Traces and Alarms

## 5.1. Tracers

### Important

Spaces were introduced in log4j category name to properly render page. Please remove them when using copy/paste.

The JAIN SLEE XDM Client Enabler uses a single JAIN SLEE 1.1 Tracer, named XDMClientChildSbb. The related log4j category is `javax.slee.SbbNotification[service=ServiceID[name=ServiceX,vendor=VendorY,version=VersionZ],sbb=SbbID[name=XDMClientChildSbb,vendor=org.mobiacents,version=1.0]]`. Where ServiceX, VendorY and VersionZ need to be replaced by the identifiers of the Service using the Enabler.

## 5.2. Alarms

The JAIN SLEE XDM Client Enabler does not set JAIN SLEE Alarms.
